

Emerging Classes in the Context of Tabular Foundation Models on Data Streams

Anonymous Author(s)

Abstract

After the Observations and the method are fixed (writing gate: self-defined stream problem, method with theory, state of the art).

Keywords

tabular foundation models, in-context learning, data streams, emerging classes, label shift

ACM Reference Format:

Anonymous Author(s). 2027. Emerging Classes in the Context of Tabular Foundation Models on Data Streams. In *Proceedings of The ACM Web Conference 2027 (WWW '27)*. ACM, New York, NY, USA, 1 page. <https://doi.org/10.1145/nnnnnnnn.nnnnnnnn>

1 Introduction

Yang-style: the stream setting in which a class emerges; Observations 1–3 lead to the question, contributions.

2 Problem: a class emerging in the context

Self-defined stream: batches, delayed labels, context budget M ; the emerging class c with n_c labelled rows in the context and share π_t in the incoming batches. Assumptions stated explicitly.

3 Observations

Obs. 1: recall of c at $n_c = 10$ is a small fraction of that at $n_c = 100$ (feasibility: 0.24 on 9 sources, 0.16 on 7 multi-class sources; Emergence log 2026-10-06). Obs. 2: prior correction (EM) recovers recall only at a large cost on the old classes. Obs. 3: no rejection signal before the first labelled row (AUROC ≈ 0.6). To be redone on streams before they enter the paper.

4 Method

Based on Confidence Amendment (Zhao et al., TPAMI 2025): an amendment schedule in n_c .

5 Theory

Assumptions, displayed statements, remarks.

6 Experiments

Streams, baselines (FIFO, EM prior correction, LTM, MICE, ...), protocol fixed before the final test.
